

You should be able to download the application from this github site.

<https://github.com/kbritrx007/RampBuilder/releases> it would be the file called something like RampBuilder_V7_7.exe select the latest version available.

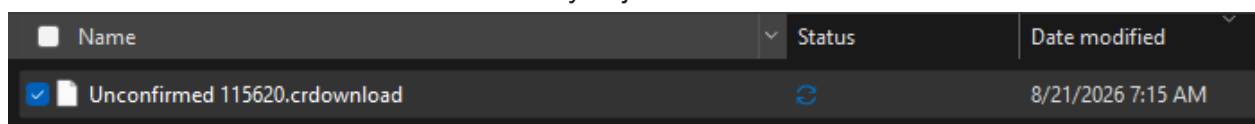

That version with Win in the version should run on a windows operating system. If you get to a screen that looks like this then we are in good shape.

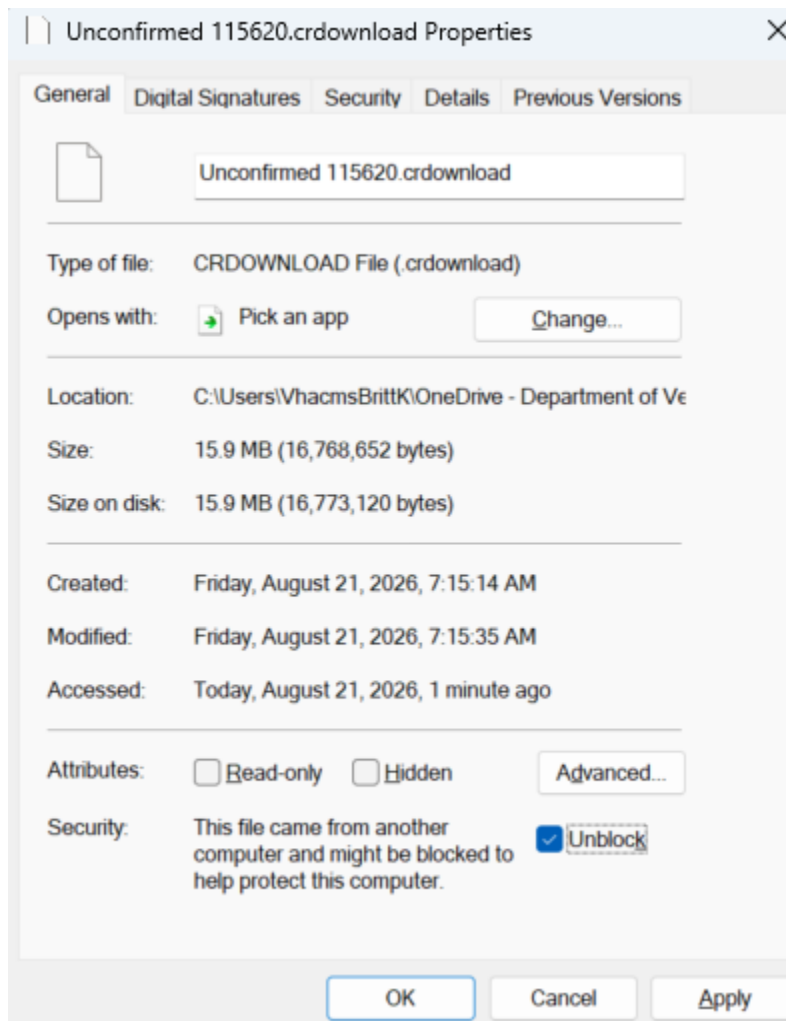

After you click to download the .exe file and select Save As and save it to your desktop, you may see this popup.

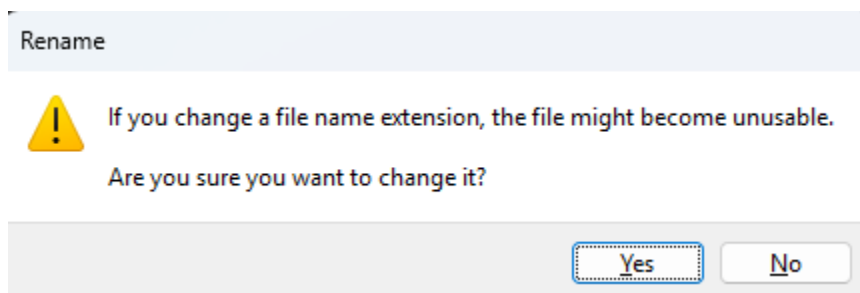

If you go to the desktop in your file explorer you'll see a downloaded file with a strange name and the date modified should be now since you just downloaded it.

Right click on the file and select Properties then check the Unblock box at the bottom of the popup and click Apply then OK.

It may make you change the file name by right clicking and selecting Rename and replace the current name with RampBuilder.exe
Select Yes on the popup about changing the file name extension.

If you aren't able to change the file extension you may need to enable that option on your computer first.

Windows 11

Open File Explorer (press Win + E).

Click View in the top menu bar.

Hover over Show and check File name extensions.

Windows 10

Open File Explorer (press Win + E).

Click the View tab in the top ribbon.

Check the box next to File name extensions.

Once enabled, file extensions (like .txt or .jpg) will appear at the end of file names. When you rename a file, simply edit the extension after the period, and click Yes on the warning prompt to confirm the change.

This should be a 1 time setup for this version and once this is done you should be able to just double click on the icon on your desktop to open the program.

Once the application is launched you may begin designing ramps!

You can add items on the left and you can click and drag things on the screen. The reference surface is the "high point" we start the ramp from (house, deck, porch, etc) so you can put that first deck or ramp up against that and that's where the elevation defaults start for the post heights. You can adjust for the terrain if it's not level but that gives the starting point since the section closest to that reference piece is seen as the "top" of the ramp. If you select an item on the canvas to move it there should be a blue outline and you can click the R key to bring up the rotate option. Once the layout looks good you can go to the post tab and click the generate posts button and then review/adjust as needed and then the same on the rail tab for the generate rails button. You shouldn't have to do any edits on the component tabs but you can make comments if needed. You can save and export the file from the file menu so you can open it later and pick up where you left off or change things. The export will open an HTML file you can print or save as a pdf to send to the group. The save option generates a JSON file you can share with other designers who may load the design on their computer from your file.
